

## **Relevance of Non-HLA Antibodies in Kidney Transplantation**

Kidney transplantation is the most desirable mode of Renal Replacement Therapy (RRT), which improves both quality of life and longevity.

The better understanding of the human immune (HLA/NonHLA) system and the availability of immunosuppression therapy have a considerable impact on the improvement of transplanted kidney and patient survival which has direct impact on patient's quality of life and health care facility.

The in-depth understanding and knowledge gained from MSc will help me to develop skills in planning, performing and deliver of the high-quality research. This enables me to complete the Research project on the role Non- HLA antibodies in the Transplantation.

The overall skills will help to transform the transplant clinical service at our centre, deliver high quality of patient centre care and enables to provide the "Right Therapy to Right Person" (Individualised Therapy).
